1.0 INTRODUCTION

This Geotechnical Data Report (GDR) was prepared specifically to present a discussion of geotechnical testing and results for a municipal solid waste (MSW) permit application (MSW Permit No. 2374) for the proposed Pescadito Environmental Resource Center facility. As depicted on **Figure 1 – Site Location Map**, the proposed facility is located within an approximate 12,194-acre ranch property, located about 18 miles east of Laredo and south of U.S. Highway 59 in rural south-central Webb County, Texas. Rancho Viejo Waste Management, LLC is seeking a MSW permit to construct a new Type I municipal solid waste management facility at the referenced site. The proposed facility is approximately 1,100 acres, which includes a municipal solid waste landfill facility (MSWLF) unit comprising approximately 800 to 850 acres.

Geotechnical exploration and testing activities reported herein were conducted by **Raba Kistner Consultants, Inc. (RKCI)**. This GDR is intended to accompany the Subsurface Investigation Report (SIR) for this permit application that was prepared under a separate cover by our affiliate company **Raba Kistner Environmental, Inc. (RKEI)**.

2.0 FIELD EXPLORATION PROGRAM

The proposed facility is approximately 1,100 acres, although the area of the proposed Type I MSWLF will comprise approximately 800 to 850 acres. As described in more detail in the SIR for this permit application, the field exploration program, which formed the basis of the geotechnical data study for this site, was accomplished in four (4) phases by our affiliate company **RKEI** from November 2009 through January 2012.

Following completion of the most recent field exploration activities in January 2012, collective subsurface characterization activities within the proposed permit boundary area had been evaluated by a total of 57 exploratory soil borings, 19 piezometers, and 2 exploratory test pits at the locations shown on **Figure 2 – Boring/Test Pit Location Map** attached to this report.

As presented on **Figure 2**, soil borings installed during preliminary study phases (Phases I and II) are designated as borings B-1 through B-26 (excluding B-9), whereas borings installed following TCEQ approval of the Soil Boring Plan (Phase III) are designated as borings B-9, B-101 through B-126, B-11A, B-109A, B-114A, and DB-1, respectively. Exploratory test pits designated as TP-1 and TP-2 were excavated in January 2012 (Phase IV).

2.1 STANDARD PENETRATION TEST (SPT)

The Standard Penetration Test (SPT) is a field procedure used to obtain disturbed samples and estimate relative density of granular material and consistency of cohesive material by driving a thick-walled sampler into the bottom of a boring at specific sampling intervals. The field test is expressed as blows per foot (BPF), which has been correlated with a variety of soil properties. A total of 29 SPTs were conducted in borings B-1 and B-2 and are presented on the boring logs provided in the SIR, **Appendix B**.

2.2 POCKET PENETROMETER

A pocket penetrometer is a small handheld testing device used to estimate the consistency of cohesive soils. Pocket penetrometer results (as Shear Strength) for borings B-2 through B-27, B-103 through B-105, B-107 through B-126, B-11A, B-109A, B-114A, and DB-1 are shown on boring logs in **Appendix B** of the SIR. Pocket penetrometer measurements were not obtained at borings B-101, B-102, and B-106. Pocket Penetrometer results (as Shear Strength) are presented on **Figures A-1 through A-78** in **Appendix A**, of this report.

3.0 LABORATORY TESTING

Laboratory testing was performed on selected samples of the soil strata encountered and recovered during our field exploration operations. Samples were selected for testing so that the engineering properties of at least one sample per soil stratum that may form the bottom or sides of potential excavations would be determined. Additional samples were tested to provide general information about each stratum.

Laboratory testing focused on classification, moisture content, and permeability testing specifically referenced in the TCEQ permitting requirements at 30 TAC §330.63(e)(5). Note that much of the classification testing was conducted on disturbed samples obtained from RotoSonic borings (Phases II and III). While disturbed samples are suitable for classification and moisture content testing, other geotechnical test results from RotoSonic samples should only be used for qualitative reference purposes. Undisturbed samples for all four strata identified in the SIR were subsequently obtained from the test pits (Phase IV) and tested for classification, moisture content, and permeability. The sections below provide a more detailed description of testing and the results.

3.1 CLASSIFICATION TESTS

Index testing such as Atterberg Limits and the percentage passing, the No. 200 sieve, were used to classify soils in accordance with ASTM Standard Test Methods D4318 and D1140, respectively. Classification tests were assigned to each soil strata visually identified during field sampling and logging to assist in the interpretation and presentation of final boring logs. In addition, classification tests were assigned to all advanced testing, (e.g., permeability). Classification test results are useful as correlative tools for other properties such as permeability. Classification tests were conducted on samples collected from each stratum (I through IV) identified in the SIR. The results of the classification tests are presented on **Figures A-1 through A-78** in **Appendix A** of this report.

3.2 MOISTURE CONTENT TESTS

Natural moisture content tests were performed in accordance with ASTM Standard Test Method D2216. Moisture content results, when combined with classification testing results, are useful as performance indicators of cohesive soils such as estimating the shrink or swell potential of cohesive materials. Moisture content tests were conducted on samples collected from each stratum (I through IV) identified in the SIR. The results of the moisture content tests are presented on **Figures A-1 through A-78** in **Appendix A** of this report.

3.3 PERMEABILITY TESTS

Permeability (hydraulic conductivity) tests were conducted in accordance with ASTM Standard Test Method D5084, Method C or falling head procedures using de-aired tap water. Permeability tests were assigned to intact undisturbed samples obtained at test pits TP-1 and TP-2. Permeability tests were conducted on samples collected from each stratum (I through IV) identified in the SIR. Samples from Strata I through IV were tested on their horizontal axis as they represent the sidewall of the proposed landfill excavation. Additionally, a sample of Stratum IV was tested along the vertical axis to represent the bottom of the proposed landfill excavation. A summary of the permeability test results are presented in tabular form on **Figure B-1** in **Appendix B** of this report. In addition, a detailed summary and graphical presentation of each hydraulic conductivity test is provided as **Figures B-2 through B-19** in **Appendix B** of this report. Note that the majority of permeability tests were performed for horizontal flow paths; the sample trimmed for a vertical flow path is indicated with “-V” as the sample number suffix on **Figures B-16 and B-17**.

4.0 STRATIGRAPHY AND SOIL PROPERTIES

The following sections address the generalized stratigraphy observed in the borings and test pit excavations performed for this study, potential uses of materials that may be excavated during construction, and typical properties of those materials. The majority of laboratory test results are presented in graphical and numerical form on the borings logs presented in **Appendix C** of the SIR.

4.1 GENERALIZED STRATIGRAPHY

The subsurface conditions encountered at the boring locations are shown on the boring logs presented in **Appendix B** of the SIR. The boring logs should be consulted for boring specific (detailed) stratigraphic information. These boring logs represent our interpretation of the subsurface conditions based on the field logs, visual examination of field samples by our personnel, and laboratory test results of selected field samples. Each stratum has been designated by grouping soils that possess similar physical and engineering characteristics. The lines designating the interfaces between strata on the boring logs represent approximate boundaries. Transitions between strata may be gradual.

Generalized soil profiles corresponding to geologic (stratigraphic) fence diagrams included as **Figures 4 through 13** of the SIR present the soil type, layer thickness, and depth to water are also presented on **Figures C-1 through C-10** in **Appendix C** of this report. An index map is provided as **Figure 3 – Fence Diagram Index Map**. These profiles depict that the majority of soils observed in the borings were cohesive in nature and the granular inclusions were sporadic and discontinuous across the site.

As presented on the referenced figures, the stratigraphic units have been designated at the site based upon review and interpretation of boring logs and geologic sections, in addition to consideration of down hole geophysical logging data, and test pit information and photographs. In general, the soils observed within the borings and test pits performed for this study are predominately cohesive in nature. Fat clays (CH) and lean clays (CL) are predominant and were observed in about 95.5% of the samples obtained during drilling operations. Test pit observations were similar. The remaining 4.5% of samples included about 2.5% cemented soils and about 2% “granular” soils. The cemented soils included thin layers of siltstones, claystones, and clay shales. Thick layers of sandstones were observed in the relatively deep

boring DB-1. The types of “granular” soils observed included silts (ML and MH), poorly graded sands (SP), clayey sands (SC), and silty sands (SM).

4.2 SOIL PROPERTIES

A graphical summary of the engineering properties for each of the four soil strata described above are presented on **Figures C-11 through C-14** in **Appendix C** of this report. The results of Atterberg Limits testing, specifically the Liquid Limit and the Plastic Limit have been presented in the first column/graph of these graphical summaries. Atterberg Limit testing includes Liquid Limits, Plastic Limits, and a resultant Plasticity Index. The Plasticity Index (PI) is simply the numerical difference between the Liquid and Plastic Limits. The PI is used in soil classification and also commonly used as a correlative tool for estimating volume change (shrink/swell), soil shear strength, and even permeability characteristics. Results of laboratory tests indicate that about 89% of samples tested for plasticity have a PI greater than 20.

The second column/graph presented on **Figures C-11 through C-14** presents the results of moisture content testing. As depth increases, the range of moisture variation decreases.

The last column/graph presents a comparison of the information presented in the first two columns/graphs. That is, the measured Plastic Limit less the corresponding measured moisture content. On the basis of these results, the in-situ moisture conditions are consistently dryer than the soil’s plastic limit, indicating:

- soils are significantly desiccated, (i.e., very dry in their present condition).
- soils could experience significant swell with increases in moisture content.
- soils are generally overconsolidated.

5.0 CONCLUSIONS

In general, the subsurface soils encountered in this study are predominately cohesive (clayey) in nature. Fat clays (CH) and lean clays (CL) are predominant and were observed in about 95.5% of the samples obtained during drilling operations. Test pit observations were similar. The remaining 4.5% of samples included about 2.5% cemented soils and about 2% “granular” soils. The cemented soils included thin layers of siltstones, claystones, and clay shales. Thick layers of sandstones were observed in the relatively deep boring DB-1. The types of “granular” soils observed included silts (ML and MH), poorly graded sands (SP), clayey sands (SC), and silty sands (SM).

The cohesive soils encountered in the borings and test pits were stiff to hard in consistency, and appear overconsolidated, (i.e., “stiff, fissured clays”). The presence of stiff, fissured clays, and their associated strength characteristics, should be accounted for in the facility design.

The cohesive soils were also highly plastic while the natural moisture contents were seven to eight percentage points (on average) below the soil plastic limit. These conditions result in a potential for shrink/swell movements with changes in the moisture content. There is a significant swell potential of the highly plastic clay with the increase in the soil moisture contents. The shrink or swell potential of the predominantly clayey soils should be accounted for in the facility design.
